

ANSWER KEY

1 Asymmetric Cryptography

1.1 Task 1

Asymmetrical cryptography (also known as public-key cryptography) works “somewhat” like this:

1. From some “random” numbers, Alice generates a pair of keys, known as the public key and the private key. Alice publishes the public key so everybody can get it. The private key stays with Alice and is kept secret by her.
2. Bob takes Alice’s key and “locks/encrypts” his message with the public key, rendering it unreadable to everyone except the private key owner (Alice). Bob then sends the encrypted message to Alice.
3. Alice can then “open/decrypt” the message with the private key.

The *key* idea in this scheme is that, the key to “lock” and “open” the message are different, hence the name asymmetrical cryptography. The main assumption is that from the public key, it is “extremely hard” to obtain the private key.

One can quantify the “(extreme) hardness” of obtaining the private key from the public key by estimating the number of years it takes to crack the message. The record for the longest RSA key length broken is 768 bits, and it took them an equivalent of almost 2000 years of computing on a single-core 2.2 GHz AMD Opteron-based computer ¹. The internet nowadays uses 1024 or even 2048 RSA-bits, and the time it takes to crack them with today technology is probably much more than the current age of the universe. So far no one has successfully crack beyond 768 bits, but if you want to try your luck, you can try ².

1.2 Kid-RSA

Kid-RSA is very similar to RSA, as it has most of the properties of RSA encryption algorithm. However, it is not secure as it can be broken by mathematicians who have studied number theory ³.

Follow these steps to implement kid-RSA:

1. Choose four “random” numbers a , b , a' , and b' .
2. Evaluate the following numbers:

¹In case you are wondering, they used a lot of computers in parallel. <https://eprint.iacr.org/2010/006.pdf>

²RSA numbers, https://en.wikipedia.org/wiki/RSA_numbers

³If you are interested, you can read about Extended Euclidean Algorithm. There is even an online calculator version in <https://planetcalc.com/3298/>

- $M = a \times b - 1$
- $e = a' \times M + a$
- $d = b' \times M + b$
- $n = (e \times d - 1)/M$

3. From these numbers, e and n are the public keys, and d is the private key.

4. To encrypt the message P , use the operation $C = e \times P \pmod{n}$.

Note that the message P is an integer and can only have values between 0 and $n - 1$.

5. To decrypt the ciphertext C , use the operation $P' = d \times C \pmod{n}$.

For those of you who are unfamiliar with the concept of modular arithmetic $y \pmod{z}$, it is the remainder obtained from dividing y by z . For example, if we wish to find $13 \pmod{4}$,

$$13 = 3 \times 4 + 1$$

The division result is 3 and the remainder is 1. Thus, we can write $13 \pmod{4} = 1$. It should not be too difficult to make the extension that the $y \pmod{z}$ is an integer between 0 and $z - 1$ inclusive.

Now, for the kid-RSA to work nicely, we require that n is an integer (see Assignment below), and that $P' = P$, by performing decryption on the encrypted message, you will obtain the original message:

$$\begin{aligned} P' &= d \times C \pmod{n} \\ &= d \times e \times P \pmod{n} \\ &= (n \times M + 1) \times P \pmod{n} \\ &= (n \times M \times P) \pmod{n} + P \pmod{n} \\ &= 0 + P \pmod{n} \\ &= P \end{aligned}$$

Note that $n \times y \pmod{n} = 0$ and P can only have values between 0 and $n - 1$.

1.3 Representation

The kid-RSA operation as described above pertains to numbers. But our messages contain more than just numbers; take, for example, the messages you send to your friends on Whatsapp or Telegram. They consist of words and special characters. To perform the kid-RSA operation above with characters or words, we need to find some way to represent those words as numbers. In the experimental session, we are using ASCII representation, but for the purpose of this exercise, we will use a simpler 26 alphabet-number representation.

For example, if you want to write the word “WORD” in this representation, it would be:

$$\begin{aligned} (\text{WORD})_{26} &= 23 \times 26^3 + 15 \times 26^2 + 18 \times 26^1 + 4 \times 26^0 \\ (\text{WORD})_{26} &= 404248 + 10140 + 468 + 4 = 414860 \end{aligned}$$

A	B	C	D	E	F	G	H	I	J	K	L	M
1	2	3	4	5	6	7	8	9	10	11	12	13
N	O	P	Q	R	S	T	U	V	W	X	Y	Z
14	15	16	17	18	19	20	21	22	23	24	25	26

Table 1: Conversion table from alphabet to number.

2 Assignment [10 pts]

Task 1 [2 pts] Verify that n is always an integer, i.e. $e \times d - 1$ is divisible by M .

$$\begin{aligned}
 e \times d - 1 &= (a' \times M + a) \times (b' \times M + b) - 1 \\
 &= a' \times b' \times M^2 + (a' \times b + a \times b') \times M + a \times b - 1 \\
 &= M \times (a' \times b' \times M + (a' \times b + a \times b' + 1)) :)
 \end{aligned}$$

Task 2 [2 pts] Find what word does the number 2490 represents in the 26 alphabet-number representation. Show your working steps.

Find the first letter:

$$2490 \pmod{26} = 20$$

20 corresponds to 'T' on the conversion table.

Find the second letter:

$$(2490 - 20)/26 = 95$$

$$95 \pmod{26} = 17$$

17 corresponds to 'Q' on the conversion table.

Find the third letter:

$$(95 - 17)/26 = 3$$

$$3 \pmod{26} = 3$$

3 corresponds to 'C' on the conversion table.

Put all the letters together.

The word is 'CQT' ! :)

Task 3 [2 pts] Try to encrypt the message $(QC)_{26} = 17 \times 26 + 3 = 445$. Show your working steps.

For the first letter:

'C' corresponds to 3 on the conversion table.

$$\text{Message} = 26^0 \times 3$$

For the second letter:

'Q' corresponds to 17 on the conversion table.

$$\begin{aligned}\text{Message} &= \text{Message} + 26^1 \times 17 \\ &= 445 :)\end{aligned}$$

Task 4 [2 pts] Try to decrypt the encrypted message obtained in Task 3, and verify that you obtained $445 = (QC)_{26}$. Show your working steps.

Find the first letter:

$$445 \pmod{26} = 3$$

3 corresponds to 'C' on the conversion table.

Find the second letter:

$$(445 - 3)/26 = 17$$

$$17 \pmod{26} = 17$$

17 corresponds to 'Q' on the conversion table.

Put all the letters together.

The word is 'QC' ! :)

Task 5 [2 pts] You overheard an encrypted message 78025 with the public keys $(e, n) = (12413, 323279)$.

Try to crack the message, and express your answers in the form of $(???)_{26}$.

Hint: You can find the private key d from public keys (e, n) from the equation:

$$d \times e \pmod{n} = 1$$

$$d \times e + k \times n = 1$$

Also, you might want to consult some mathematicians to do this task.

Visit this website: <https://planetcalc.com/3298/>

Key in the public keys (e, n) in the calculator. We obtain $d = 10756$ and $k = -413$.

Since $P' = d \times C \pmod{n}$,

$$P' = 10756 \times 78025 \pmod{323279} = 4616$$

By using the methods from Tasks 2-4, the message is "FUN". :)
